

Function of the lc-ms interface

Overview

Overall, the interface is a mechanically simple part of the LC-MS system that transfers the maximum amount of analyte, removes a significant portion of the mobile phase used in LC and preserves the chemical identity of the chromatography products (chemically inert). Coupled chromatography-MS systems are popular in chemical. Therefore, it is crucial to have an interface to connect the LC outlet to the MS inlet that can efficiently transfer the LC mobile phase to gas and at the same time ionize the analytes. Various interfaces for LCMS were developed, but issues with sensitivity, stability and user-friendliness were. The basic components of a LC unit consist of: (4) Detector - for the analysis of the separated components in a sample. Examples of common MS detectors are electron multiplier and. Liquid chromatography/mass spectrometry (LC/MS) is an analytical technique that combines the separation power of liquid chromatography with the direct mass measurement of a mass spectrometer as the detector.
