

How much signal attenuation does an optical splitter cause

Overview

Optical signals lose power (attenuation) as they travel through fiber—typically 0.2 dB/km for single-mode fiber at 1550 nm (the primary PON wavelength). A higher split ratio means each output port gets less initial power, limiting how far the signal can travel. Optical splitters play a crucial role in Fiber to the Home (FTTH) Passive Optical Network (PON) systems, efficiently distributing a single optical signal to multiple destinations. The split ratio and insertion loss are two key parameters defining their performance. A deeper understanding of these. For example, for the loss (attenuation) in a segment of optical fiber we have the value at the input of the segment and at its output. Understanding how much loss splitters introduce is. By dividing a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at users' homes, splitters eliminate the need for dedicated fibers to each residence—slashing infrastructure costs while scaling network reach. They cover FBT couplers and PLC splitters that can split the optical signal into several parts at a certain ratio.
