

How to compact and backfill fiber optic cable trenches

Overview

Microtrenching is a method of installing fiber optic cables, HDPE ducts, and Microducts by creating a narrow trench, usually less than an inch wide and up to 12 inches deep. The trench is then filled with a special grout back-fill material that provides stability and support to the. Underground cables are pulled in conduit that is buried underground, usually 1-1.2 meters (3-4 feet) deep to reduce the likelihood of accidentally being dug up. In extreme cold climates, cables may need to be buried at greater depths where there temperatures are colder and frost penetrates to. This offers substantial benefits over traditional methods as it involves using a diamond circular saw to cut a 0.5 inch wide, 4 inch deep trench. Unlike conventional approaches that require digging deep, wide trenches, micro trenching involves creating narrow, shallow cuts in the road surface or sidewalk. It forms a critical backbone for modern communication networks across both urban and rural environments. For On-Demand Concrete, this usually means one of our volumetric concrete mixers is on site.
